TorC vs ΛCDM is prior-dominated — DESI DR2 BAO, 1000 live points

All three have $|\Delta \ln Z| < 1$: **inconclusive** on the Jeffreys scale. The data do not distinguish the models, so the Bayes factor is set by the prior on ς — it even changes sign. Widening the prior *lowers* the evidence: that is the Occam factor. At $\lambda = 2$ the typical ς is 3 while the posterior wants $\varsigma \approx 1.4$, so most prior volume is wasted. No single number here is "the" Bayes factor.
